This file describes the main steps to compile the ros2_ws on the Raspberry

The raspberry Pi does not have the resources to compile the whole workspace at the same time. It is better to compile the packages one by one (some packages can take 20 minutes to compile..)
In any case, the first package to compile is the "interfaces" package because the other packages depend on it.
The compilation must ALWAYS be launched at the workspace root (~/ros2_ws)

Syntax of the compilation command (`colcon build`): * `colcon build` to compile all the workspace * `colcon build --packages-select "NameOfThePackage"`

1. Compilation of the "interfaces" package

```
cd ~/ros2_ws
colcon build --packages-select interfaces
```

2. Then, you can compile the other packages:

```
cd ~/ros2_ws
colcon build --packages-select carla_msgs
colcon build --packages-select can
colcon build --packages-select joystick
colcon build --packages-select car_control
colcon build --packages-select imu_tools
colcon build --packages-select imu_filter_madgwick
colcon build --packages-select imu_complementary_filter
colcon build --packages-select simulation
colcon build --packages-select system_check
```

3. After the compilation, you have to source the ros environment:

```
source ~/ros2_ws/install/local_setup.bash
source /opt/ros/humble/setup.bash
```
